

What does AI-Driven Development mean to you?

AI-Driven Development, as the name suggests, is a type of development where Artificial Intelligence (AI) or a Large Language Model (LLM) is at the core of the process. Instead of a coder simply writing code alone, AI can provide assistance, write code on their behalf, and help them bring ideas to life as quickly as possible. With AI's assistance, a developer can write code more easily and faster.

How do you see the future of Human–AI Collaboration in software development?

The future of Human–AI Collaboration depends on how quickly humans adapt to partnering with AI. If a human learns and embraces the new AI technology quickly, it can certainly help them create something productive that they could not have created alone or would have struggled to create.

With the latest AI technology, a person who doesn't even know how to write code can create amazing software with an AI assistant; all they need is the knowledge of how to build it conceptually.

Adapting to the new AI era can be challenging if one views AI as a competitor. Instead of seeing it as competition, people must change their mindset and view it as a partner that can help build very interesting things if given the chance.

We are already using AI, and its role has changed drastically today compared to the past. In the past, it was often used as a conversational bot for answering questions, but today it is a versatile tool. Whether it's web

searching, creating programs from scratch, or performing complex coding tasks, you can do it all with AI.

Ultimately, humans must adapt to this technology because it not only works seamlessly but can also help perform various tasks efficiently.
